Entered as Second-Class Matter, Nov. 22, 1920, at the Post Office at Highland, N. Y.

The LANDING GEAR and TAIL SKID, shown above, attached to an **AEROMARINE 39'B' HYDRO**, a number of which the Navy are offering for sale at **\$1500⁰⁰** each, make a *fast flying, slow landing, reliable* aeroplane procurable at a very low cost; an *excellent* machine for *passenger carrying*. This Landing Gear & Tail Skid complete is being furnished by the *Aeromarine Plane and Motor Company*, Keyport, N.J., for **\$500⁰⁰** F.O.B. Factory. *Prompt deliveries* can be made on a few sets of this equipment.

MINIMIZING REPAIRS

The new models of WRIGHT engines have shorter expanding valve heads and increased cooling around the valves. This has stopped valve weeping. From 100 to 500 hours may be expected without regreasing valves. A new device makes engine timing an easy operation.

FROM now on all WRIGHT engines will have this nameplate on the hub. This is a visible guarantee to all who fly with the engine that it was made by us in our own plant. This plate certifies that every ounce of material was critically examined, then purchased by our own experienced men to exact gauge and carefully assembled. The nameplate guarantees the engine has passed our exacting running test requirements. While we are building aircraft engines this vigilance will never be relaxed.

†

The seven absolute requirements for aircraft engines are fulfilled in the new models of Wright engines now in production and being sold.

ENGINE REQUIREMENTS

1. Lightness per horsepower
2. High power
3. Low fuel consumption
4. Short overall length
5. Incompressible parts
6. Longevity

RESULT IN PLANE OPERATION

Greater useful load, increased performance.

Speed, climb, power reserve.

Economy, long travel radius, increased useful load.

Increased maneuverability, compact installation.

No long repair periods, economy, safety.

Many WRIGHT engines built four years ago are still flying. Many have flown over 10,000 miles and over 10,000 hours. E-4 and E-5 engines incorporating changes based on actual experience from thousands of our own engines, no other commercial types to figure on almost a life of some hours.

The reliable WRIGHT engines safeguard the life of the plane they protect quality and not requirements. Still, experience and increasing vigilance make these engines the most reliable in the world.

Compare the characteristics of these stock engines now in production with any engine built—foreign or domestic.

	WRIGHT E-4	WRIGHT E-5
Power at 2000 R.P.M.	125 H.P.	125 H.P.
Weight, dry with hub	200 lbs.	200 lbs.
Oil per H.P. hour	4.5 lbs.	4.5 lbs.
Overall length, including hub and prop.	4' 10"	4' 10"

NOTE.—The power given is the mean road power, many industrial engines give higher power and lower consumption.

No Blocks

GLENN L. MARTIN Airplanes have one outstanding advantage that neither automobiles nor locomotives can ever have.

Every method of land transport is strictly limited by the conditions of the road bed. Cloud burst, wash-out, or fallen bridge will hold up mail, express, or fast freight for hours, and sometimes for days.

These delays are paid for in time stolen from production, increased overhead, and lost earning capacity.

The airplane sails aloft unhampered. Its road is the shortest distance between two points. Its speed, the greatest which man has ever achieved.

If your business has imperative needs for speed in transportation, discuss your problem with us.

Aid to Aviation

FACING a situation with many points similar to the American aviation problem the British Air Ministry has recently announced a new plan for encouraging the maintenance of the British cross-Channel service. A fund of £200,000 a year for three years has been provided, which includes the £50,000 subsidy under which the present British companies, Handley Page Transport, Ltd. and Imvies Air Line, are operating. Actual payments to the operating companies are to be at the rate of 25 per cent of their annual gross earnings.

The most interesting feature of the plan is the provision for the placing of orders by the Air Ministry with construction for "modern converted types". The machines so constructed are then to be rented by the government to "approved firms" at a monthly rental of 3% per cent of the cost of the machine. After thirty such payments the machine becomes the property of the operating company. While it is possible that a machine after thirty months would become obsolete if not obsolete, the operating company will have paid 25 per cent of the depreciation charge while the Government has paid 25 per cent. In effect the company gets the machine on the installment plan for 75 per cent of its original cost.

Another provision is for insuring the machines by the operating companies in force of the Air Ministry against loss or damage by accident resulting from operation, as well as normal insurance against fire, etc.

There is neither reason for nor prospect of the American aircraft industry receiving any direct government subsidy. Without a direct subsidy a method suggests itself whereby the government through the agency of the Post Office Department can lay a real foundation for commercial air transportation and at the same time make the air mail service self-supporting. First the department could advertise a competition for mail carrying machines for specified routes. With approval of certain designs a number of the machines could immediately be ordered. The machines that make good would then be allocated to operating companies with whom the department would establish contracts. The machines would remain the property of the government, their costs to be absorbed in the price of the mail contract. In other words the capital of a company operating with government machines would be conserved strictly for operating expenses. The cost of insurance also might well be borne by the government and in the same way absorbed in the cost of the contract.

At the same time our military needs would be served by creating an aircraft industry which could quickly be directed to war aviation in the eventuality of such a necessity arising. Which again proves that the successful prosecution of our next war will depend on the survivability of our commercial aircraft industry to a war industry.

Flying by Instruments

THERE have long existed two schools of thought among airplane pilots, the first maintaining that it is dangerous and undesirable for a pilot ever to depend on instruments to guide him in his flying while the second has advocated the use of instruments on every possible occasion. In the pre-war days of exhibition flying, when piloting was regarded largely as an acquired instinct, instruments found little favor, but the tendency has been more and more towards the use of instruments not only for navigation but for guiding the pilot in the actual flying of the airplane. This trend is likely to grow as airplanes grow larger and the pilot's accommodations become more completely enclosed, the functions of the commanding officer of a large airplane approximating more and more nearly to those of a captain of a ship. The necessity of instrumental assistance in cloud-flying is now generally conceded. The lack of faith in instruments which many pilots feel and which leads them to advocate the entire elimination of instruments for training machines is largely due to neglectable past errors in design and installation which have led to false indications. The instrument designer has a great responsibility for the failure of aerial navigation and for his own share in that failure, and those who are responsible for the planning and production of airplanes should not overlook any opportunity of co-operating with the instrument companies in carrying that responsibility.

Further Education

THE daily press has just lately rendered a service to aviation—perhaps unconsciously, but nevertheless a service.

Two unfortunate accidents happened practically simultaneously. One on the sea in a seagull craft, and the other also on the sea, but in an aircraft. In the former accident many lives were lost while in the latter none were lost. Both accidents were due to storms, but the aircraft was able to avoid the storm sufficiently to warrant its passengers being saved while such was not the case with the steamer.

The daily press published simultaneously, from four accounts of both these accidents, and thus showed the public that aviation, though still young as compared with sea travel in steamers, can still profitably lay claim to safety on a means of transport.

We wonder how many of the American public read these two accounts in the press, and as a result made up their minds never to set foot in an airplane; thus in the next thought made arrangements for their vacations, many of which will include sea voyages with their accompanying perils which in view of the happening mentioned above seem every bit as likely to materialize into accidents as those of air travel.

The British Aerial Derby

The British Aerial Derby was flown at Hendon, Airmount, London, on July 16. Led the list of entries with their extreme range of power he landed at it is understood that two men were flown over the same course at the same time—the Derby and the Handicap. The entries were started according to their handicaps. The first machine to complete the course won the Handicap while the machine covering the course in the least time won the Derby.

The start and finish of the race were at Hendon, and the course was over 250,000 mile circuit with five turning points.

The men were under the auspices of the Royal Aero Club which awarded the following prizes: Derby winner, \$600 (\$3,000) and trophy; Handicap winner, \$300 (\$1,500) and trophy; second, \$150 (\$750), and third, \$75 (\$375).

THE MARE I WITH MR. JAMES, THE PRIZE, STANDING BY IT COVERING THE DERBY.

The machines entered with their engines, pilots and handicaps were as follows:

MACHINE AND ENGINE	PILOT	HANDICAP h. m. s.
Avery Baby, 35 hp. Green	Tally	1 35 42
Avery Baby, 35 hp. Green	Hadden	1 17 34
Southport Pigeon, 50 hp. Rhoads	Forster-Walsh	37 6
British Tanager, 230 hp. 556-600	Baker	37 6
Day-Pass		
Avery Viper, 220 hp. Hispano-Tail-Cut		32 30
Spain		
Southport Comet, 130 hp. Clugnet	Broad	30 3
SESA, 180 Hispano-Suiza	Longton	28 6
SESA, 180 Hispano-Suiza	Ortveder	28 6
Southport Nighthawk, 300 hp. Nieuport		17 04
A.B.C.		
Martinsville, 200 hp. Hispano-Fast		22 18
Spain		
British Bullet, 400 hp. British Union		7 42
Mare I (Daniel), 450 hp. Napier-James		6 42

(The machine was virtually scratch on account of the withdrawal of M. Sals Laroselle's entry which was actually scratch.)

The winner of both the Derby and the Handicap was the Mare I piloted by Mr. James at 160 m.p.h. The machine was designed by Mr. Foland and built by the Gloucestershire Aviation Co., and has received the premier nickname of "Daniel" although just why it bears this name cannot be seen from the lines of the machine. It is noteworthy that the SESA which actually finished first but was disqualified because of a faulty turn by Mr. Ortveder, and the Southport Nighthawk piloted by Pitt L. Nieuport which was well in the running until forced to land just short of the finish due to lack of fuel were also designed by Mr. Foland. In connection with Pitt L. Nieuport's bad luck it is interesting to note that both Mr. Ortveder's SESA and Mr. James's Daniel were surprised in 1915 fuel tank that their engine stopped for lack of it while the machines were going it to land.

It was unfortunate that the two French entries were withdrawn on account of accidents during testing as they both

would undoubtedly have put up very creditable performances. Furthermore, mention need hardly be made of the regret, and the cause thereof, of the late Mr. Howlett's absence from the race with the Rumpolt Godard's he was to have flown.

MR. ORTVEDER, PILOT OF FIRST DISQUALIFIED MACHINE THE PIERRE.

Conclusion Service

Fights between France and Canada, in Morocco, are now being made free from a week, and a daily service is being planned. The trip from Paris requires two days, largely because passengers from Paris must go by rail to Toulouse. Air trips from London to Canada cost slightly more than 40 pounds, while the rail and water journey costs a little more than twenty pounds. The passenger, however, needs four days in time.

A Modified Le Pere Fighter

A MODIFIED LE PERE FIGHTER. NOTE THE WING DRIVEN FUEL PUMPS AT THE REAR OF THE LOWER WING—MAIN WING.

A prominent California sportsman, Mr. L. C. Bond had a Le Pere Fighter which he wanted modified for pleasure flying and racing, at the same time retaining the original structural lines of the machine. The work has been done to the design of G. Edw. Barnhart, an Accredited Engineer of Pasadena, Calif. The requirements which Mr. Barnhart had to meet with the redesign of the machine, and his manner of meeting them were as follows:

1. The machine was to land at less than 60 m.p.h. with no change in maximum speed.

In order that the machine might land slowly it was necessary to increase the surface of the stabilizer so as to produce the proper stalling action as the machine had previously had flying speed of 75 m.p.h. This increase added the structural changes when there was a change of load and modified painting was necessary to bring up the color of the stabilizer and struts so that they might be more effective at small angles.

It is interesting to note that through the stabilizer surface was increased, no change in top speed was detected during the tests; despite the fact that it showed slightly less by calculation. In the trials the machine did not lose flying speed even below 50 m.p.h. and had an horizontal slow speed of 63 m.p.h. at 3000 ft.

2. The machine was to carry pilot alone or with one or two passengers. In any of these cases it did land, or a light load of fuel and oil was to be carried without the machine being either too fast or too heavy with the power on or off and without the use of the stabilizer adjusters.

To satisfy the condition of varying load, a stabilizer adjuster already on the machine was used with modification. This set the stabilizer for any particular load.

3. With the power on or off the machine was to fly at high or slow speed without nose or tail becoming wobbly and without requiring an adjustable stabilizer while in the air.

In satisfying the condition for slow speed (see first condition) a part of this problem was overcome. The main loading on the tail surfaces due to shift of the center of pressure could be taken care of, but it was desirable to shift the center of gravity in relation to the thrust line, and to shift the thrust line itself in relation to the center of gravity to avoid an over-

coming the difficulties in that the thrust would not require as much load on the tail surfaces.

At high speed horizontal flight condition the engine thrust was under a negative angle of one degree.

4. If possible, the structure of the machine was to be lightened.

It was found that by having new surfaces—the elevator, stabilizer, and ailerons—made of aluminum and be materially lightened. The tail end assembly was also lightened. To have lightened other parts of the structure at this time would have delayed the progress of reconstruction more than was desirable.

5. The free movement of the aileron system was to be lightened because it did not produce useful results.

In the first modification there were gears attached to the control shaft and connected to the main structure. This caused more friction. The gears were removed. The control shafts were connected. The control shafts were connected. The control shafts were connected.

THE FUEL SYSTEM OF THE MODIFIED LE PERE FIGHTER.

was attached to the lower cylinder with only a spreader between the cylinders. This spreader ran from the top of the lower cylinder to the bottom of the upper cylinder, which caused the upper and lower cylinders to have radically different centers which was quite unsatisfactory.

To correct this condition a quadrant was used on the piston shaft shaft with external wires and pulleys since it was not practicable to open the valve spring covering as to put the Le Prieux bell crank system in place.

6. A new fuel system was to be installed to provide:
 - (a) Fuel actually delivered to the combustion under pressure without pressure on the main supply tank.
 - (b) An auxiliary air pressure system for use in emergencies.
 - (c) Gravelly flow in the carburetor.
 - (d) Delivery of fuel by either of two pumps.
 - (e) Drainage of the main tank without interference with the other tanks.
 - (f) Fuel flow in any system of pressure or gauge from any tank.
 - (g) Fuel flow with a factor of safety.

The layout of the fuel system as shown will make place its advantages.

The pumps are of the air-driven centrifugal type. They deliver 120 gallons of fuel per hour. The centrifugal pumps will show pressure but they will not build it up beyond their capacity in hold it. A fuel flow bypass is installed to lead the pressure at any desired point. The air pressure pump in the Standard Liberty equipment. An air bypass is used to regulate the pressure on the tanks.

The gauge showing the fuel pressure is located as far as possible with a very slight curve, the actual pressure at the carburetor. Should there be a stoppage in the line between the gauge and the carburetor, the reading for this pressure will not be correct.

The mechanical drive and rubber hose connections are used. Soft annealed one-half inch rubber tubing replaced stainless flexible hose of a diameter smaller than one-half inch.

Any tendency to ground loop in landing was to be removed as far as possible.

The rubber surface was increased in order to give better control on the ground. The rubber which was on the outside was of steel tire structure. To save time these tubes were simply extended for maintenance. However, this structure might have been lightened materially.

The action of the tail sled was also changed to help to overcome any tendency to ground loop.

8. The machine was to land with a short run. The tail sled was made to rest more on a track to check forward action and slow the machine up on the ground. It now dug into the ground rather than slides over it.

9. Any tendency to nose over in soft ground was to be removed as far as possible.

By slowing up the machine the tendency to nose over was greatly lessened. The angle between the wheels and the

center of gravity was increased. This change was made by a shift in the location of the center of gravity back vertically and longitudinally.

10. The tail sled was to have a full spring action. This was accomplished by springing the tail sled on rubber cushion wheels.

11. The side indicators were to be removed so that the pilot might have unobstructed view the landing and ground signs. The indicators are now mounted on the side of the body with their tops just reaching the upper lip of the fuselage.

12. A sufficiently large flow of oil lubricates the two 7½ gal. tanks was to be provided so the machine was an oil tank and the sled on the other.

This oil flow was provided for by the installation of a 2½ in. pipe between the tanks to replace the ¾ in. pipe.

13. A portion of the balanced part of the elevator was to be removed because they did not allow sufficient fuel and was slightly overbalanced.

The over-balancing was eliminated by the construction of new elevators.

14. When the engine was throttled quickly or for a prolonged period of time, the inverted direction of the exhaust manifold caused the gas to hang in the rear or low end of it causing a minor explosion in the manifold and a flaming fire on the exhaust pipes. This was to be removed.

The Standard Liberty pipes were used with the springs to the rear. This eliminated the trouble.

Mr. G. G. Harding was Mr. Harbo's personal representative on the work of remodeling, and he was responsible for many changes and improvements. Mr. Harbo states that the machine is now due to fly and that it handles a great deal better than a D-14.

The engineering and design work done by Mr. G. G. Harding, who was employed as consulting engineer. The actual rebuilding was done under the supervision of Mr. L. O. Stern, representative of the C. K. Little Aircraft Co. of Pasadena, Calif.

New Airplane Co.

The Harboring Airplane Co. has been incorporated in Pennsylvania by C. F. Bower, Walter R. Sake and Robert E. P. Bower all of Harboring, Pa.

Anderson, Ohio, Aero Club

The Aero Club of Anderson has been organized with the following officers: Ed. Wallace, Pres.; J. B. Chapman, Vice-pres.; Harold Walters, Treas.; and Florence Brubaker, Sec. The club is not yet in a position to take up active flying and is now the time being plan to confer the interests in furthering the cause of aviation.

Senators Urge Nation to Save Millions by Increasing Air Defense Over Sea

Bombing Tests Show Vulnerability of Battleships and Imperative Need of Aircraft Carriers

Extracts from the remarks of Senators Walsh, Hatcher, King, Bradley, and Jones of the Senate during the debate on the Aircraft-Battleship Rebuilding bill of July 31 (Congressional Record, August 6, 1933, pp. 5031-5034.)

SENATOR WALSH OF OREGON DELIVERED

Senator Walsh:—"We are expending now about \$400,000,000 upon the Navy, and since the expiration of the Vapour coast I have been concerned in the expenditure of about \$100,000,000 of it in a way that will not add any security to the people of the United States. The expenditure of the Vapour coast demonstrated that what the best minds of the naval life of England have conceived for the last year and a half, that the battleship is practically obsolete."

SENATOR KING OF CALIFORNIA DELIVERED

Senator King:—"We are building sixteen battleships, costing from \$40,000,000 to \$120,000,000 apiece, and in less than thirty months, as Gen. Mitchell told me he would, they will sink the ships which Mr. Wright and we are now building. Yet the airplane development is just beginning. It is just in its youth. War, more, it has not accomplished anything compared with what it will accomplish, according to those who are concerned, even with this next year. So we go forward building those great battleships at this enormous expense, knowing that made of two years the airplane will have rendered this particular type of battleship absolutely worthless as a defensive preparation."

Senator Walsh:—"Mr. President, there are six of those great battleships of the 'Indiana' class, costing from \$40,000,000 to \$120,000,000 apiece to build, upon which very little work

before the aircraft service has even reached that it contends in its first period of service in these waters."

Senator Vandenberg:—"Under the Senator's reasoning would it ever be possible to land an army on foreign soil, provided that the Nation spent sufficient money to have airplanes capable of covering the landings of which the Senator speaks?"

Senator Walsh:—"The Senator has suggested a very important proposition. An official stated to me a few days ago that not only the expenditure of the Virginia coast demonstrated that the battleship is not to be new being built, but practically obsolete, but it demonstrated that the battleship with sufficient airplane and submarine protection, the country was perfectly safe from attack from any other country."

SENATOR TROTTENBERRY FROM ARIZONA

Senator Tamm:—"There shows, too, that while possibly the airplane would not do vital damage to a battleship by striking on the deck, but it would absolutely destroy transports carrying troops."

Senator Walsh:—"Yes. Of course Mr. President, it might be referred from something I have said that I would like to see some building ship orders, regardless of what other nations do. I do not take that position. I do not wish that to be understood. What I say is that we are putting this vast amount of money into these ships without getting any corresponding security and without getting any safety such as we are entitled to have for that amount of money. We had lightly better take \$40,000,000 out of these battleship expenditures and put it into airplanes and submarines if we want real security and real safety. I do not think in the

Editorial in New York Times, July 23, 1933

Of the sinking of the former German dreadnought Outboarded by army aviators, General Williams, Chief of Ordnance, said: "A head was first being that will be heard around the world." He added: "The capital ship now faces a new menace that must be guarded against by every possible study and effort." As the practical way to guard against that menace is to equip our air force equal or superior to that of any other sea power, it devolves upon Congress to supply the necessary appropriations. The alternative, it should be emphasized, is limitation of armaments by agreement with other nations.

Read men who hold that the heavily armed battleship would withstand assaults from the air and remain afloat have been misled. It was only a question of the airplane power of the land coast. Brig. Gen. William Mitchell's dictum that "the air force will constitute the first line of defense of the coast" is no longer correct. If a single modern ship could be sunk by a single airplane, the United States Navy would be in a position to take up active flying and to lay the time being plan to confer the interests in furthering the cause of aviation.

A nation unprepared to concentrate her whole air force over the water, if the decision has been, can just as well leave her ships tied up to the shores instead of sending them to certain destruction against a hostile country equipped for the purpose.

If there were no interference with a non-armed Power possessing no airplane carriers, and a well-trained and numerically strong aviation corps, the United States fleet could not face the risk of sailing to sea, and it would be in great danger of being sunk at its moorings. Little comfort can be put out of the view that under certain conditions the Outboarded ship might probably have escaped destruction. If a single modern ship could be sunk by a single airplane, the United States Navy would be in a position to take up active flying and to lay the time being plan to confer the interests in furthering the cause of aviation.

Twenty-one minutes of attack sufficed to sink the once formidable Outboarded, and the seven 2,000-pound bombs that were dropped. It was not necessary to burn her deck up. The bombs that exploded caused the ship to sink. The Outboarded ship was dropped alongside. Who my loved could have conceived the desperate power of these airplanes? The achievement was a great triumph for the intelligent, strong-willed, persistent Assistant Chief of the Army Air Service, a leader who will be remembered to take any greater task than he is willing to face himself. It is pleasant to remember that Brig. Gen. William Mitchell was among the many who by his planning and his planning in the

In a contribution to the Navy World's Work Editorial line and—"If the status of the airplane advances can be realized, it seems that any battleship operating within the radius of planes which are in control of the air will be disabled or destroyed." If these claims have not been fully realized, no fair-minded officer will deny the fact that the expenditure of a considerable naval air force is not more important than the completion of the three-year capital ship construction program.

THE LE PRIEUR PORTER BEFORE DEPARTURE. THE MACHINE IS SHOWN FITTED WITH A SUPERCHARGER ON THE ENGINE

has been done, upon which a very small percentage of building has been accomplished, and if we want to save, we'd not be wise to discontinue the building of those six battleships of the Indiana type, not only to slow down, but to interrupt the building. There has already been given—and only to slow down, but to abandon and close up the contract. If it costs \$10,000,000 to close up the contract, very well and good, we will have saved \$230,000,000 or more by doing that. If it costs \$40,000,000 or \$60,000,000, we will have saved \$200,000,000 or more by doing so, and in my opinion, unless we are willing to do that, Mr. President, unless we are willing to tell the Army to 100,000 men and recognize the official recognition of the Army, and unless we are willing to take the losses which we have had given to us off the Virginia coast, and discontinue the building of at least six or eight of these battleships, there is no place where we can cut any expenditures that will amount to anything considerable."

First Break Was Fast

Senator Jones—"Mr. President, I had the privilege of seeing the building of that German battleship, and I heard some of the expert naval officers talking with reference to that ship and the character of its construction before it was sunk, and one of them said that, in his judgment, it was a thousand to one that the ship would not sink by the sinking. He was thoroughly acquainted with the character of the construction, with the watertight compartments, and all that sort of thing; and yet, as the *Seydlitz* from Lihke has sunk, within 15 or 20 minutes from the dropping of the first 2,000-pound bomb the ship was sunk."

Shaw Wants of Money to Continue Building Battleships Now

Senator Borah—[Senator Borah went into the record as advised from the *New York Times* which is reproduced elsewhere on this page]. "Mr. President, without assuming to say that the battleship is absolutely obsolete and can never be made effective by any changes which may be made in any different construction, which may be made, it does seem to me conclusively established that to go forward and build these battleships at this time until the testing proposition has been carried to its final conclusion, and that the battleship will stand it, is a mere show waste of money. No man in the Senate, as a business man, a member of a corporation, a stockholder, or having anything to say with reference to the building of a battleship, would consent to it for a moment. He would say, 'Let an know whether we are putting \$42,000,000 into each one of these ships that can be sunk in 20 minutes

building of battleships we are giving our country any security or any safety at all, comparatively speaking.'"

Strength and Endurance Greatly Impaired

Senator King—"I think these tests demonstrated the vulnerability of the battleship, and demonstrated that, while it is not obsolete, as the principal aim of it is lost, its strength and endurance have been greatly impaired."

Nations in Agency of Fate

Senator Tamm—"It looks as if the Senator from Idaho will understand that I am in complete and ardent harmony with him as to the vital importance of the matter to which he calls the attention of the Senate and the country. The nations of the world, as the Senator from Idaho has so much better said than could I, are in an agency of oppression and war. The necessities of the people and the demands of the Governments have created the luxuries for the home."

Save \$100,000,000 and Have Better Navy

Senator Borah—"Mr. President, the party which is now in power can not afford from any standpoint, to permit any opportunity to go by to reduce expenses to the point where it can be shown that there is income saved, indeed, it will be unwise if it can be maintained even at the present rate. I hope, therefore, when the resolution which I have offered goes to the committee it may have an immediate consideration of it and an immediate report on it. It ought not to require long to consider the resolution. The whole matter was discussed a few weeks ago in this Chamber, every Senator's opinion is made up, and if the resolution can be accepted and passed and the Army satisfied as it proposes, it would be a vast saving in that particular."

"Then, if the Naval Committee would report out the bill which has been introduced by the able Senator from Utah [Mr. King] to continue that attack, [Senator King has proposed converting six battleships, under construction, into aircraft carriers, to be equipped with paravels, bombing and other types of airplanes] we should have an expedition in that direction of some \$200,000,000, and still have a better Navy than we shall have by the expenditure of that sum. If there is any other way by which we can save, I do not know of it. We may cut out some expense here and there in a department, or we may decrease a few supplies and carried on in such manner as the Secretary of the Treasury says we must in order to hold taxes even to the present status which we do it upon these two lines."

Gordon Bennett Balloon Race

The Aero Club of America has received the following correspondence for consideration on the Gordon Bennett balloon race on September 10, 1932:

I. A. Shipping of Material.

The material must be shipped prepaid to the following address:

CARE TOUR ET TAXIS,
AERO CLUB DE BELGIQUE,
71 AVENUE LOUISE,
BRUSSELS, BELGIUM

B. Material will be charged from the above address to a barge to be chosen by the Aero Club of Belgium.

C. Material will be insured against fire and theft, from the moment it leaves the customs house until the moment of departure from the field by the organizing club.

D. The material must be at the place of destination on or before September 10th, at the latest.

E. Composition of The Material Besides The Balloon itself. Every competitor must file The Following:

A. 20 meters (about 65 ft.) of gas filling hose of 300 or 350 mm. (about 12 or 14 in.) diameter

B. At least 200 bags for inflation

C. Gas bag, constructed in such a manner that after it has been used it cannot be tampered with.

D. The Belgian Club also advises to bring a lifting wagon

III. The Log. Will be furnished by the Belgian Club and contains special instructions for the Pilot.

IV. Inspection of the Material

The measuring of the cubic contents of the balloons by the Sporting Committee of the Aero Club of Belgium will take place beginning September 12th.

The competition will be present on that date.

V. Picking the Balloons.

It is necessary that the filling of the balloons start September 17th at 3 p. m.

VI. Lights.

To conform to the Aerial Traffic Laws the balloons must carry during the night the red light being a white light 5 meters (about 15 ft.) below the basket visible from all directions from a distance of at least 5 kilometers (about 3 miles).

VII. Signals.

Every balloon must carry the personal flag of its club and its national flag

THE BIRMINGHAM-BIRMINGHAM AIRCRAFT IN FLIGHT

The accompanying photographs show in advantage the Birmingham-Birmingham Aircraft in different stages of flight. The machine, the make and description of which appeared in the July 25 issue of AVIATION AND AIRCRAFT JOURNAL, has been undergoing tests at Corpus Field, Long Island. Four test pilots, Bert Arnold, Randolph Park, Lloyd Bernard, and Charles Overton have tested the machine and submitted reports of its satisfactory performance. Corcoran is at present conducting a series of tests of 15 lb. flying time over a period of two weeks.

The question of possible breaking of the propellers arose in the consideration of the design of the Airline. Engineering E. H. Corcoran says that he has not seen such a machine elsewhere. Furthermore, he says that the machine fly well enough on one engine to enable an emergency landing field to be reached in case of necessity, and that there is no turning moment sufficient to make control of the machine difficult. In that connection it is interesting to learn that the Airline is being tested with temporary engines. The machine was loaded for 1,000 hp. such as would be developed by two 500 hp. Packard engines or two power Liberty engines of that type or motor. The present direct drive Liberty was installed simply to expedite testing and thus verify the type before securing the more expensive engine.

All at the cost of the present test engine system trouble was experienced with the result that the engines had to be changed to 1,000 rpm. at which speed the horsepower of the Liberty is less than 300 h.p. However engine system trouble has now been overcome and better results secured.

The Log of the machine to date shows 34 flights of from 19 mi. to 15 mi. duration; the total time in the air being 15 hr.

The Airline is so obviously a commercial machine, and such an innovation in design—especially the lifting fuselage—that results of tests with the proper engine will be interesting along the increase in performance which will result with the increase in power.

Wind Tunnel Construction*

By J. H. Perkins and B. C. Crane

The wind tunnel at Toronto University is of the standard 4 ft. N.P.L. type and is installed in a hydraulic laboratory which is 90 ft. x 113 ft. x 17 ft. 6 in. This is well above required size of building for a wind tunnel of this type. The laboratory however contains a large amount of apparatus and bulky equipment such as engines, pumps and tanks, while a line of columns down the center facilitated placing the wind channel of course.

As a result of these unavoidable features the flow of air in the room was very much disturbed, and an investigation was undertaken to determine the best form of intake to reduce the turbulence and secure a uniform distribution of velocity over the working cross section.

A large number of intake arrangements were tested of different types. The intake as finally adopted is in the form of a box equal in cross-section to the outside of the bellmouth. It is 5 ft. 5 in. square and projecting 50 in. from the face of the latter. The sides and front are made up of latticed gratings of $\frac{1}{8}$ in. x $\frac{1}{8}$ in. square stock, spaced at a distance apart of $\frac{1}{4}$ in. in order to secure a directive effect on the air. The gratings are of the simpler slot construction as used in the later N.P.L. distributors. The flow gratings are secured together and to the bellmouth by four horizontal bars. Projecting from the corners and the mid points of the sides of the intake are eight guide blades parallel to the channel axis. They are of $\frac{1}{4}$ in. thick, three ply laminated wood supported on light iron knuckles. The cover blades are 15 in. and the sides are 12 in. wide and 20 in. long. The eight guides are fastened across the front of the intake in a star formation.

The investigation shows that the intake secures a satisfactory air stream under conditions very adverse from an aerodynamic point of view.

*Abstract of University of Toronto aerodynamic research paper No. 1.

The "Bristol" Ten-Seater Airplane

Key Devices

Behind the engine a steel floor-plate bulkhead has been fitted, and all control connections pass through glands. No fuel is carried in the body of the machine aft of this bulkhead. In the roof of the machine a special emergency exit is provided, measuring 2 ft. 3½ in. x 2 ft. 2 in. This is operated by a quick release gear should occasion arise.

Specifications

Dimensions		
Length, Overall	34 ft. 9 in.	
Wing	45 ft. 6 in.	
Height	11 ft. 0 in.	
Weights		
(1) As Passenger Machine		5,820 lbs.
Shipping Machine, with water		6,000 lbs.
Fuel & Oil, full 400 gal. (200 gal. standard)		740 lbs.
Over (1)	1 8 00 00	
Emergency (2)	1,275 lbs.	
Passage (40 lbs. per passenger)	4,000 lbs.	
As Cargo Machine		6,000 lbs.
Shipping Machine, with water		6,000 lbs.
Fuel & Oil, no store		591 lbs.
Over (1)	4,000 lbs.	
Cargo	5,250 lbs.

Speed at 10,000 ft.	100 m.p.h.	100 m.p.h.
Time to climb to 10,000 ft.	22 min.	17 min.
Climb	1,000 ft. p. min.	675 ft. p. min.

The Bristol Ten-seater Airplane is a single engine, tandem biplane having an enclosed cabin for eight passengers and an open cockpit for pilot and mechanic.

Engine Installation

The Napier 450 hp. engine which is fitted, is on a readily detachable mounting which can carry the main radiator and oil tank. Complete access to the engine can be obtained without removing its self-locking fasteners, so part of the work being removed from the machine.

Engine starting is fitted and also hand turning gear supplied from the ground.

Cabin

The cabin is entered through a door aft of the lower plane and seats five of the passengers in regular rows, with two chairs, the other three facing aft. The seats are collapsible and when folded project only five inches from the cabin sides, leaving a maximum of floor space if it is desired to carry cargo in lieu of passengers.

Windows, which can be opened, are fitted the full length of both sides of the cabin, and heating is provided by means of hot air ducts round the exhaust pipes. For the convenience of passengers seats are arranged in a small recessed, self-sealing house has been provided in close proximity to each seat. These fold against the side of the cabin and are readily accessible, the waste pipe discharging through the floor.

When it is desired to use the machine singly for the transport of cargo the space available is height 38 ft. 6 in., height at center, 5 ft. 9 in., width 4 ft.

Pilot's Cockpit

The roomy cockpit in which the pilot and mechanic are accommodated is situated between the fire bulkhead and the front spar of the top plane. An exceptionally fine field of view is thus provided.

Engine Hatch

Below the pilot's cockpit is a compartment 4 ft. 6 in. long x 4 ft. wide x 2 ft. 6 in. high, accessible through a trap door in the underside of the fuselage. This is intended for the acceptance of passengers' baggage or for other suitable cargo.

Fuel System

The two main fuel tanks, of 50 gal. capacity each, are hung under the bottom plane at the inner interplane struts. Fuel is drawn from either of these tanks by two Venturi-controlled pumps coupled in series, and delivered through a Venturi hand gauge to the carburetor, very carefully adjusted to a 38 gallon gravity tank and overflowing back to the particular main tank in use. "Scoutie" capacity gauges for both main tanks are fitted on the instrument board.

Landing Gear

The landing gear is of the four-wheeled Obo-elastic type, with wheels in tandem, broken being fitted to the rear wheels and operated by a car type brake lever in the pilot's cockpit. A gate is provided for the brake lever so that the wheels may be operated together or singly as required.

Flare traps are used for expansion and the static pressure has been designed for ready removal of these traps. The Obo plungers are fitted with a special type of tapered handle valve to control the passage of the oil through the plunger to give constant oil pressure throughout the stroke of right motion.

Firing Controls

Single control of the wheel type is fitted, all cable pulleys being five inches diameter.

Tail Trimming Gear

The tail incidence can be varied by a lever and quadrant adjacent to the pilot to trim the machine under all conditions of speed and load distribution.

Radio

The use of radio telegraphy and telephony in the Air Service is becoming increasingly more important, as shown by the radio activities of the Engineering Division at McCook Field. Many types of radio apparatus are being tested and experimented with in the Radio Laboratory.

Work at this time is being done on various types of apparatus, including a 3-kilowatt spark transmitting set which has a range of about 1800 miles, a 3-kilowatt tube set which has a range of about 600 miles, a 3-kilowatt telephone set which has a range of several hundred miles, as well as various smaller radio telephone sets which have ranges of from 15 to 100 miles. In addition to this apparatus tests are also being conducted with telegraph and telephone apparatus, which is used on airplanes and includes a telegraph set having a range, from airplane to ground, of 100 miles and various telephone sets having range of from 15 to 100 miles. This is the course of tests it is possible to carry on communication from the radio laboratory with an airplane which is flying at a distance of 50 miles from the field as easily as it is to carry on conversation over the ordinary wire telephone from the house to the office.

In addition to communication, radio is also being used in the Air Service today for the purpose of assisting in navigation, particularly in the case of short-throw flying. Its means of direction finding loop stations located on the ground, it is possible to ascertain the bearing and the location of any airplane that is flying in the vicinity. Thus, if an airplane is flying above the clouds and it is doubtful as to its exact location, the aid a operator in the airplane only these ground direction finding stations and sets that are employed as to how whereabouts. These ground direction finding stations immediately take bearings on the airplane, and by means of triangulation determine its location. This information is then transmitted to the airplane by either radio telephone or radio telegraph.

By means of special radio direction finding loops installed on an airplane, it is possible to fly directly towards any radio transmitting station. Thus it is possible for airplanes to run above the clouds and to fly directly to another station without seeing the ground until its arrival and landing.

One of the other tests for bombs is that on a square surface built of concrete. This surface is 100 ft. square and five feet thick, one foot of heavy grouting and one foot of sidewalk materials cement, which, of course, is extremely hard. In this test, as in the other, bomb runs are filed with sand to weight, to determine their carrying ability.

There are several sets of high panels around a circle fifty feet in diameter where the officers in charge of the experiments learn the velocity of fragments from the explosion. This is accomplished by placing a vertical grade of paper over holes in the panels. Bomb panels are used in finding the value of the fragmentation bombs. These panels, however,

A SNAKE BOMB

are only six feet high, whereas the other run to 30 and 35 ft., and are so arranged as to show the effect of fragmentation bombs when employed against troops in the field. Paper is pasted over these panels and the distribution of the dust from the bomb recorded after each test is dropped.

The bombing experiments at Aberdeen have been conducted with all types of new weapons to gather information of value in fixing the standard types and sizes. The British Government has been particularly active in the development of aerial bombs, and the impact of these bombs that have been in use at Aberdeen, weigh 1,650 lb. The largest American bomb so far in use exceeds that size by 500 pounds. These British bombs are much different in appearance from those adopted in the American standard. They look much like the ordinary old water bomb, riveted together. The American bombs are carefully shaped, with radars and other appliances to give accuracy in fire.

The testing of bombs at Aberdeen is going on constantly. On one day four bombs dropped 22,500 lb. of bombs in a series of tests. The main activity, of course, was just prior to the bombing tests of the Virginia Capes, where reconnaissance was being prepared and tested for these experiments. It is a tribute to the character of this reconnaissance to reveal that out of all the bombs dropped by the Army only one of them, weighing 800 lb., was a "dud." The Navy was much less fortunate in its record.

It is the opinion of ordnance experts that there is no end to the use of effective bombs that may be constructed, except the ability of airplanes to carry the load. Bombing from the air must be regarded as in its infancy, with the promise of more startling events in the future.

Japanese Propellers

A report in the Osaka Mainichi Shimbun states that a Japanese company at present manufacturing planes and engines has been designated as a factory to manufacture propellers. Whether the designation has been made by the government, or whether the company has merely decided to take up the manufacture of propellers as a business policy, the report does not state.

CABIN OF BRISTOL TEN SEATER

Airplane Notes

Trenton, New Jersey

The Canadian Air Board announces the installation of the Air Harbor Lounge of the Eastern Canada Air Lines' airplane at Trenton, New Jersey. The airplane is 1 1/2 miles N. E. of the city on the north river road, was open to the public, and marked by a right-angled cross in a square.

Trenton, Ont. Co.

The Canadian Air Board announces the installation of the summer Air Harbor Lounge of the Empire Marine & Airways, Ltd., airplane and the name to this company of a public aviation Air Harbor Lounge for the same airplane, which is 8 miles N. of Lake Ontario on the N. E. side of the city, and are marked by a square enclosing a circle, both of which are divided in half by a line.

Atlantic City, N. J.

The Curtiss Aeroplane & Motor Corporation has two stations at Atlantic City, one for hydroplanes, located at the inlet, at the extreme eastern end of the boardwalk, the other for landplanes located about one-half mile inland, at the other end of the city, alongside the principal boulevard leading out of Atlantic City.

The water station, for hydroplanes, can be distinguished by the name on the roof of a large brick building. There are two airplanes at the airport for landplanes. Supplies can be bought by mail at the Curtiss Flying Station.

Buffalo, N. Y.

The Curtiss Aeroplane & Motor Corporation Field at Buffalo is located 7 miles northward of the city and about 2 miles east of the large bend in the Niagara River northward of the city of Buffalo.

The field is easily distinguished from the air by a long straight runway, long runs must be taken in landing, as there are several cross ditches, these are, however, marked by red flags.

The field has two hangars and is open from April 1 to December 1. Supplies and services are available.

Garden City, L. I., N. Y.

The Curtiss Aeroplane & Motor Corporation reports that the Garden City Field is located about 21 miles from New York, between the towns of Garden City and Hempstead, about 5 miles southeast of Hempstead Harbor, which is plainly visible from the air.

The field is open at all times to the public, and service and repair facilities for all types of machines are available at the field or at the factory, which is one-half mile distant.

The field may be distinguished by the buildings located on the sides, and near the water, which are white, with the name of the field in large white letters on one of the roofs.

Buffalo, Tex.

The McWren Aviation Company has leased a landing field at the end of the city wharf, less than a mile from the heart of Dallas, Texas, where they expect to carry on various flying activities, including aerial transportation, flying instruction, aerial photography, etc.

The field is in charge of Pilot McWren, former army pilot at Mitchell Field, and under the supervision of the Southern branch of the Curtiss Aeroplane & Motor Corporation, which furnishes instruction.

Trinity Springs, Ind.

Trinity Springs, Martins County, Ind., has established a municipal flying field. Pilots are invited to make free use of the field, where fuel and oil may be obtained. Trinity Springs is known as a prominent Indiana health and rest resort with an excellent hotel. The field is located at the northwest corner of the grove surrounding the springs and bathing pool.

The Grand-Walker Aerial Service of Oakland City, Ind., is at present operating from Trinity Springs field.

Lawton, Okla.

Report has been received of the establishment of a commercial airplane at this city. No details as to the location and general marking of the field were yet available, but it is understood that a company will be operating from it and that hangar space, fuel, and oil will be available.

Aero Club of America

THE AERO CLUB OF AMERICA is the one authoritative body representing national and international aeronautical affairs.

The purposes of the Aero Club of America are directed to the advancement of all phases of aeronautics, including military and naval activities relating to national defense, the development of commercial aviation, the air mail service, the enactment of federal legislation governing aerial navigation, and the industrial and technical progress of the art and science of aeronautics.

As a non-partisan and constructive force for the national good, its influence is being extended to every state, every county, and every local community, and reorganization makes membership possible to all those everywhere, who are interested in aviation.

Through affiliation with the Federation Aeronautique Internationale, direct contact exists with the aircraft activities of all other countries of the world.

Members are kept in touch with world progress in aircraft, and the best organized thought of the country upon aeronautical issues will be transmitted to the legislative branches of state and federal governments.

That our country may acquire and maintain leadership in this newest and fastest means of transportation, so intimately interwoven with all future plans for our national security and defense, is the desire of every American. You can render direct aid and support to this important end, by putting the weight of your influence into the work, through membership in the Aero Club of America.

Application for Aero Club of America Membership

To Membership Committee of the

AERO CLUB OF AMERICA

I desire to signify my interest in Aeronautics by applying for membership in the Aero Club of America, and I agree to abide by its rules and requirements.

The Laird Swallow

American First Commercial Airplane

AT times of holiday and community celebration the features often include stunts and joy rides in Laird "Swallows". But the real popularity of the "Swallow" is shown by the number of these airplanes that are being profitably used in every-day business by owners who look but to two features — performance and economy. The "Swallow" is proving profitable to distributors as well as to owners.

The K. L. Fuel System For Airplanes

Consists of ONLY TWO MAJOR PARTS:

1. A hand fuel pump for starting, and
2. An engine driven fuel pump for continuously supplying fuel to the carburetor at constant pressure.

A single pipe line from fuel tank to carburetor, with two pumps in series, is the only piping used.

A positive supply of clean gas, at constant pressure, under all running conditions and plane positions is absolutely guaranteed.

The faults of other systems are completely eliminated.

No more gravity tanks, return lines, air pressure or main tanks, multiplicity of leaky pipe connections and fittings, or other sources of trouble and danger.

The former complex systems of "plumbing" may now be replaced with an extremely simple and reliable system which meets every requirement.

Full information may be had from the

K. L. AUTOMOTIVE SPECIALTIES COMPANY

52 Vanderbilt Ave., New York City

FAITH

The Dayton Wright Company believes in aviation -- foresees with calm assurance the services which aircraft will render to Commerce and Industry.

It is pleased to consider that the opportunity to share in the development and in the accomplishment of its expectations of the aircraft industry is both a privilege and a trust.

Permit us to study your transportation problems. Probably you are one who may profit by the use of aircraft.
